**Borametallatomimetics – Activation of Small Molecules by Low-valent Boron Species**

The activation of small molecules is generally associated with transition metals (TM) and constitutes the basis of catalysis. It was believed that TM catalysts are required to facilitate processes such as the activation of H\(_2\) and other unreactive substrates. However, recent years have witnessed exciting developments in main group element chemistry, and the discovery of carbenes, FLPs and heavy main group species that are capable of TM-like activation reactions.\(^1\)

Our ongoing studies on borylenes, diborones, and diborynes have shown that these low-valent species exhibit a very rich chemistry, which is distinctly different from that of common compounds deriving from boron in oxidation state +3. Particularly interesting is the metal-like behavior of some borylenes and diborones, which form CO complexes analogous to TMs, bind H\(_2\) and unsaturated organic substrates under mild conditions and even activate N\(_2\).\(^2\)
